1 Problem statement

About the Client

The client in this data mining project is a tour & travels company that is offering travel insurance package to their customers. This new insurance package also includes COVID-19 coverage for their flights. However, the client wants to know which customers based on their data base history are potential purchasers who may be interested in buying this new insurance package. Previously, the insurance package was offered to some of the customers in 2019 and data was collected from the performance and sales of the package during that period. The sample data given has close to 2000 customers from that period. The client is requesting information on which customer are most likely going to buy the travel insurance given their information such as employment type, income level, etc.

Business Problem

The client may use the solutions presented to them for customer-targeted advertising of the new travel insurance package. Also, data visualizations provided will help derive interesting insights about their potential buyers in order to optimize marketing strategies.

Data Mining Problem

- A supervised classification task, where the outcome variable of interest is *TravelInsurance* that indicates whether the customer will buy the travel insurance. Performance metrics should take in consideration the positive class of buyers/purchasers.
- Find out interesting patterns and trends for better customer segmentations through data exploration and visualizations.
- An unsupervised task, where the goal is to cluster customers.

3 Data Set

Data Dictionary

1. **Age** - Age Of The Customer
2. **Employment Type** - The Sector In Which Customer Is Employed
3. **GraduateOrNot** - Whether The Customer Is College Graduate Or Not
4. **AnnualIncome** - The Yearly Income Of The Customer In Indian Rupees[Rounded To Nearest 50 Thousand Rupees]
5. **FamilyMembers** - Number Of Members In Customer's Family
6. **ChronicDisease** - Whether The Customer Suffers From Any Major Disease Or Conditions Like Diabetes/High BP or Asthama,etc.

7. **FrequentFlyer** - Derived Data Based On Customer's History Of Booking Air Tickets On Atleast 4 Different Instances In The Last 2 Years[2017-2019].
8. **EverTravelledAbroad** - Has The Customer Ever Travelled To A Foreign Country[Not Necessarily Using The Company's Services]
9. **TravelInsurance** - Did The Customer Buy Travel Insurance Package During Introductory Offering Held In The Year 2019.

Python code:

[3]:
```
# Load data set
df = pd.read_csv("../../Data/TravelInsurancePrediction.csv")

# First few rows of data set
df.head(3)
```

[3]:
```
   Age               Employment Type GraduateOrNot  AnnualIncome  \
0   31             Government Sector           Yes        400000
1   31  Private Sector/Self Employed           Yes       1250000
2   34  Private Sector/Self Employed           Yes        500000

   FamilyMembers  ChronicDiseases FrequentFlyer EverTravelledAbroad  \
0              6                1            No                  No
1              7                0            No                  No
2              4                1            No                  No

   TravelInsurance
0                0
1                0
2                1
```

---

4 Exploratory Data Analysis (EDA)

- Graphical and non-graphical representations of relationships between the response variable and predictor variables

---

4.1 Exploring Response Variable - TravelInsurance

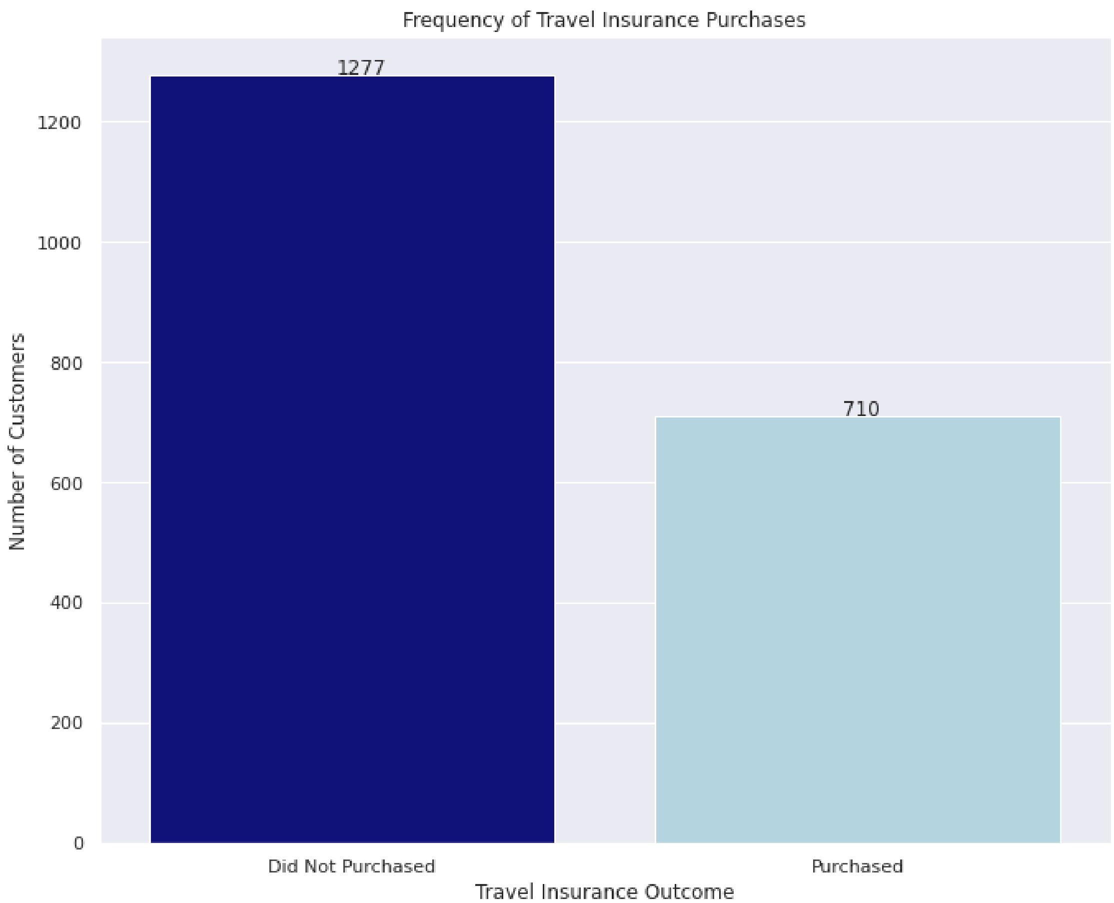
- Examine the frequency of travel insurance purchases
- 0 = No
- 1 = Yes

Python code:

[4]:
```
# Graph count plot of Non-Purchases vs. Purchases
ax = sns.countplot(data=df, x="TravelInsurance", palette = ["darkblue",␣
↪"lightblue"])

# Add count labels
for p, label in zip(ax.patches, df['TravelInsurance'].value_counts()):
    ax.annotate(label, (p.get_x()+0.37, p.get_height()+0.15))

# Graph Properties
plt.title("Frequency of Travel Insurance Purchases")
plt.xticks([0, 1], ["Did Not Purchased", "Purchased"])
plt.xlabel("Travel Insurance Outcome")
plt.ylabel('Number of Customers')
plt.show()
```



Summary

- There is a higher number of customers who flew without buying travel insurance in this sample data set.

4.2 Examing customers' Age

- Age distributions
- Age with Target Variable Overlaid
- Normalized Histogram with Target Overlaid on Age
- Age Group Comparisons (20s vs. 30s)
- Percentage of Purchases between Age groups (20s vs. 30s)

4.2.1 Age Distribution

Python code:

[5]:
```
# Get a range of customer ages
age = pd.DataFrame({'Age': df['Age'].value_counts().sort_index()})
age
```

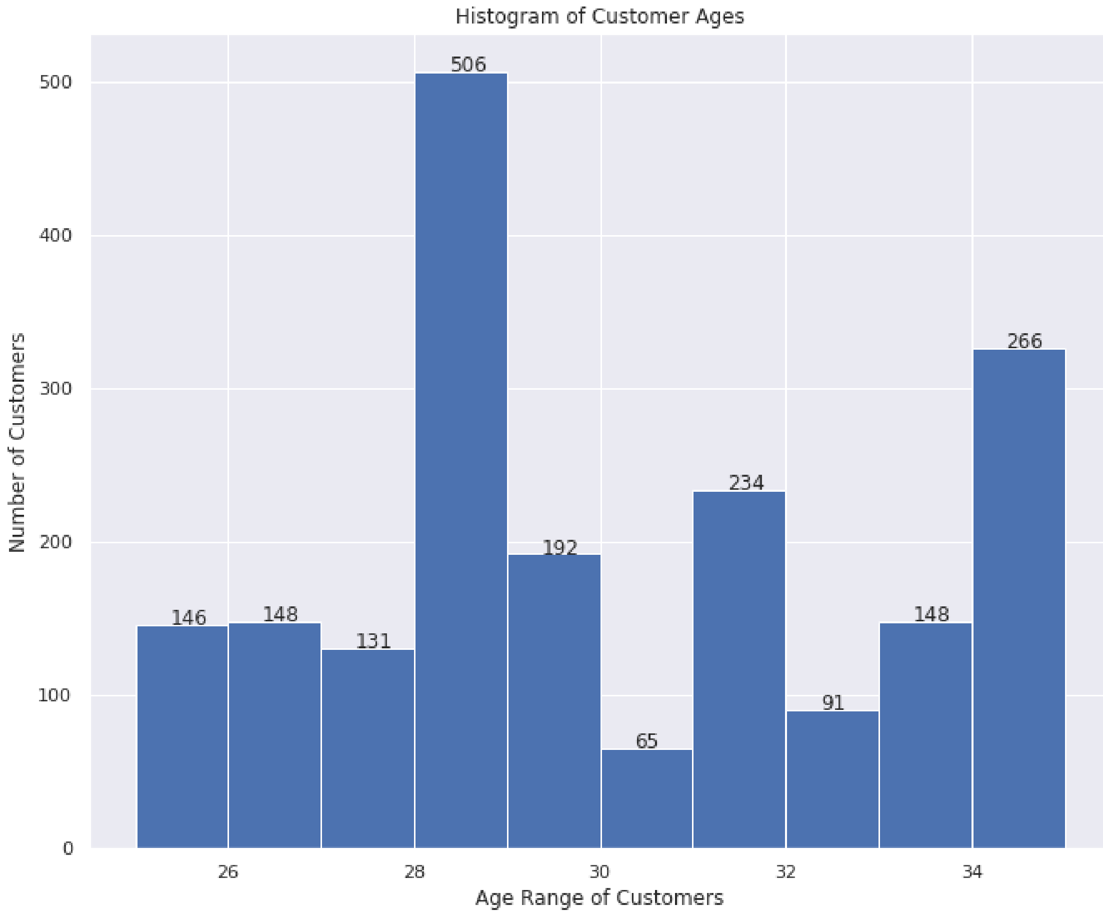
[5]:

	Age
25	146
26	148
27	131
28	506
29	192
30	65
31	234
32	91
33	148
34	266
35	60

[6]:
```
# Histogram of Age and set the range of bins from 25-35
bins = np.arange(25, 36)
ax = df['Age'].plot.hist(bins=bins)

# add labels
for p, label in zip(ax.patches, df['Age'].value_counts().sort_index()):
    ax.annotate(label, (p.get_x() + 0.37, p.get_height() + 0.15))

# title and axis
plt.title("Histogram of Customer Ages")
plt.xlabel("Age Range of Customers")
plt.ylabel("Number of Customers")
plt.show()
```



Summary

- There are 506 customers who are 28 years-old which is visualized as the most in this data set
- While customers who are 30 years-old are the least in this data set.

4.2.2 Age with Target Variable Overlaid

Python code:

[7]:
```
# Set up plot with response overlaid
n, bins, patches = plt.hist(
    [
        df[df['TravelInsurance'] == 1]['Age'],
        df[df['TravelInsurance'] == 0]['Age']
    ],
    bins=10,
    stacked=True,
    color=["lightblue", "darkblue"],
)
```

```python
# title and axis
labels = ["Travel Insurance Purchased", "Non-purchase"]
plt.legend(labels)
plt.title("Histogram of Customer Ages Travel Insurance Overlaid")
plt.xlabel("Age Range of Customers")
plt.ylabel('Number of Customers')
plt.show()
```

Summary

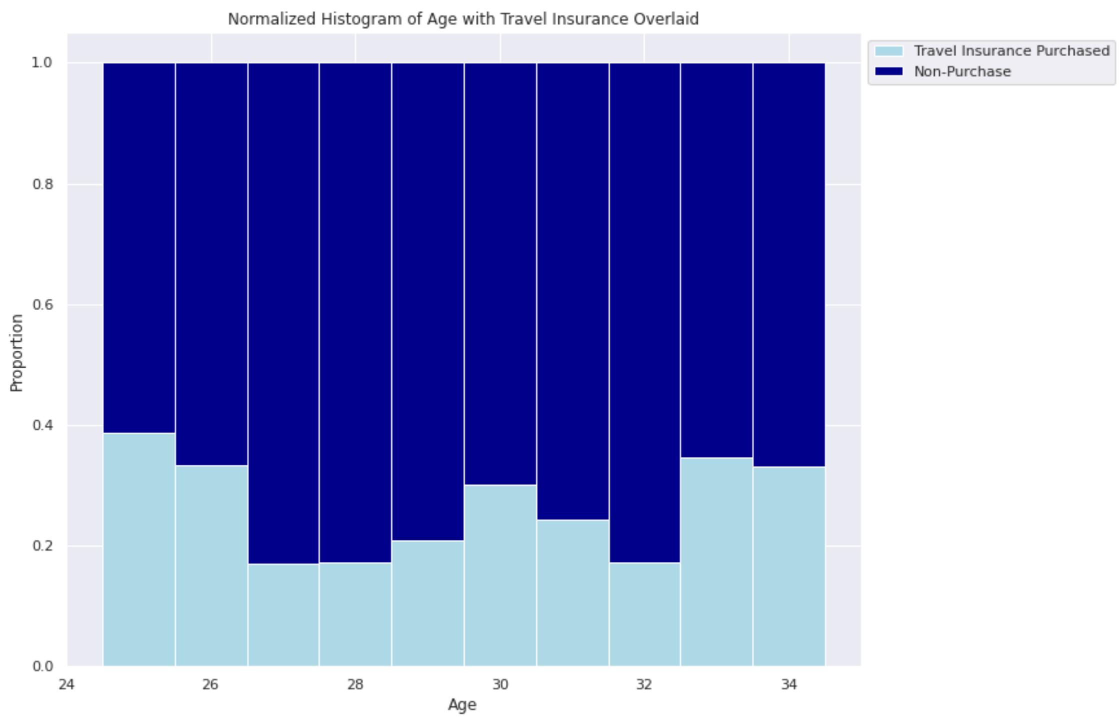
- It is difficult to compare between age groups with target variable overlaid
- Therefore, it is better to focus on one class from the target variable and analyze age in a normalized histogram.
- The following is visualized below.

4.2.3 Normalized Histogram with Target Variable Overlaid on Age

Python code:

[8]:
```
# Create normalized histogram for age groups by target overlay
n_table = np.column_stack((n[0], n[1]))  # stack the tables
n_norm = n_table / n_table.sum(axis=1)[:,
                                       None]  # create normalized tables by sum
ourbins = np.column_stack((bins[0:10], bins[1:11]))  # create table bins

p1 = plt.bar(x=ourbins[:, 0],
             height=n_norm[:, 0],
             width=ourbins[:, 1] - ourbins[:, 0],color = "lightblue")  # first␣
 ↪bar chart
p2 = plt.bar(
    x=ourbins[:, 0],
    height=n_norm[:, 1],
    width=ourbins[:, 1] - ourbins[:, 0],  # second bar chart
    bottom=n_norm[:, 0], color = "darkblue")
# Annotate legend, title with x and y labels
plt.legend(['Travel Insurance Purchased', 'Non-Purchase'],
           bbox_to_anchor=(1, 1))
plt.title('Normalized Histogram of Age with Travel Insurance Overlaid')
plt.xlabel('Age')
plt.ylabel('Proportion')
plt.show()
```



Summary

- Insights for this graph show that it may be better to compare age classified into 2 groups instead such as customers who are in their twenties (20s) vs customers in their thirties (30s).

4.2.4 Age Groups Comparison (20s vs. 30s)

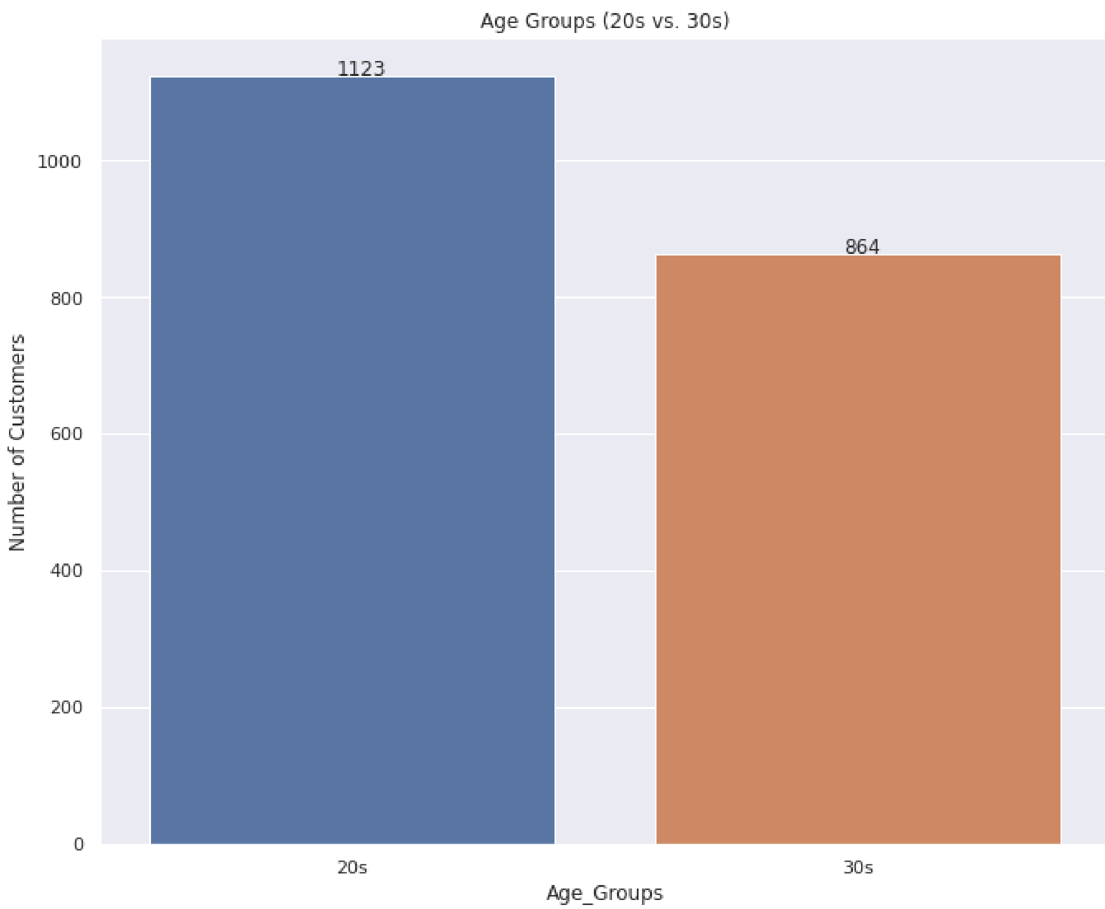
Python code:

[9]:
```
# Create function to categorize age groups
def age_groups(x):
    '''
    x: This is a value from df['Age']
    returns each as a new categorical value of 20s or 30s
    '''
    if x < 30:
        return '20s'
    else:
        return '30s'

# Apply age_groups function on each value
age_groups = pd.DataFrame(
    {'Age_Groups': df['Age'].apply(lambda x: age_groups(x)),
     'AnnualIncome':df['AnnualIncome'],
    'TravelInsurance':df['TravelInsurance']})

# Graph count plot of age groups (20s vs. 30s)
ax = sns.countplot(data=age_groups, x="Age_Groups", order=['20s', '30s'])

# add labels
for p, label in zip(ax.patches, age_groups['Age_Groups'].value_counts()):
    ax.annotate(label, (p.get_x()+0.37, p.get_height()+0.15))
plt.title("Age Groups (20s vs. 30s)")
plt.ylabel('Number of Customers')
plt.show()
```



Summary

- Before visualizing the target variable overlaid, we can see here that after binning age into two groups, there are more customers who are in their 20s than customers in their 30s in this data set.

4.2.5 Percentage of Travel Insurance Purchases on Various Features

Python code:

[10]:
```
def make_stacked_barcharts(df, x):
    '''
    Takes in a data frame 'df' and a column 'x'
    and returns a stacked bar chart of the column
    with the percentage of purchases overlaid

    '''

    # Calculate total counts from both groups
    total = df.groupby(x)['TravelInsurance'].count().reset_index()
```

```python
# Calculate total counts from only purchases
purchase = df[df.TravelInsurance == 1].groupby(
    x)['TravelInsurance'].count().reset_index()

# get percentages for purchases
purchase['TravelInsurance'] = [
    i / j * 100
    for i, j in zip(purchase['TravelInsurance'], total['TravelInsurance'])
]

# get percentages
total['TravelInsurance'] = [
    i / j * 100
    for i, j in zip(total['TravelInsurance'], total['TravelInsurance'])
]

# bar chart 1 -> top bars (group of 'TravelInsurance=0')
bar1 = sns.barplot(x, y="TravelInsurance", data=total, color='darkblue')

# bar chart 2 -> bottom bars (group of 'TravelInsurance=1')
bar2 = sns.barplot(x,
                   y="TravelInsurance",
                   data=purchase,
                   color='lightblue')

# add legend
top_bar = mpatches.Patch(color='darkblue', label='Non-Purchase')
bottom_bar = mpatches.Patch(color='lightblue',
                            label='Travel Insurance Purchased')
plt.legend(handles=[top_bar, bottom_bar],
           bbox_to_anchor=(1.05, 1),
           loc=2,
           borderaxespad=0.)
# Aesthetics
plt.title("Percentage of Travel Insurance Purchases by " + x)
plt.xlabel(x)
plt.ylabel("% of Purchases")

# Change ticks on x-axis for ChronicDiseases column
if x == "ChronicDiseases":
    chronicdiease = [0, 1]
    labels = ['No', 'Yes']
    plt.xticks(chronicdiease, labels)

# show the graph
plt.show()
```

[11]:
```python
# Call stacked bar chart function
make_stacked_barcharts(age_groups, 'Age_Groups')

# Make stacked bar charts on various columns
plot_columns = [
    'Employment Type', 'GraduateOrNot', 'ChronicDiseases', 'FrequentFlyer',
    'EverTravelledAbroad'
]

# Plot each column
for i in plot_columns:
    make_stacked_barcharts(df, i)
```

Summary

- There is a higher proportion of customers in their 30s that purchased travel insurance.
- There is a higher proportion of customers who works in a private sector or is self-employed that purchased travel insurance.
- There is no significant difference in proportion between customers who are a college graduate or not that purchased travel insurance.
- This also applies to customers with or without chronic diseases that purchased travel insurance.
- However, there is a higher proportion of customers who are frequent flyers and/or have traveled abroad that purchased travel insurance.

4.3 Monthly Income (Indian Rupee) Range

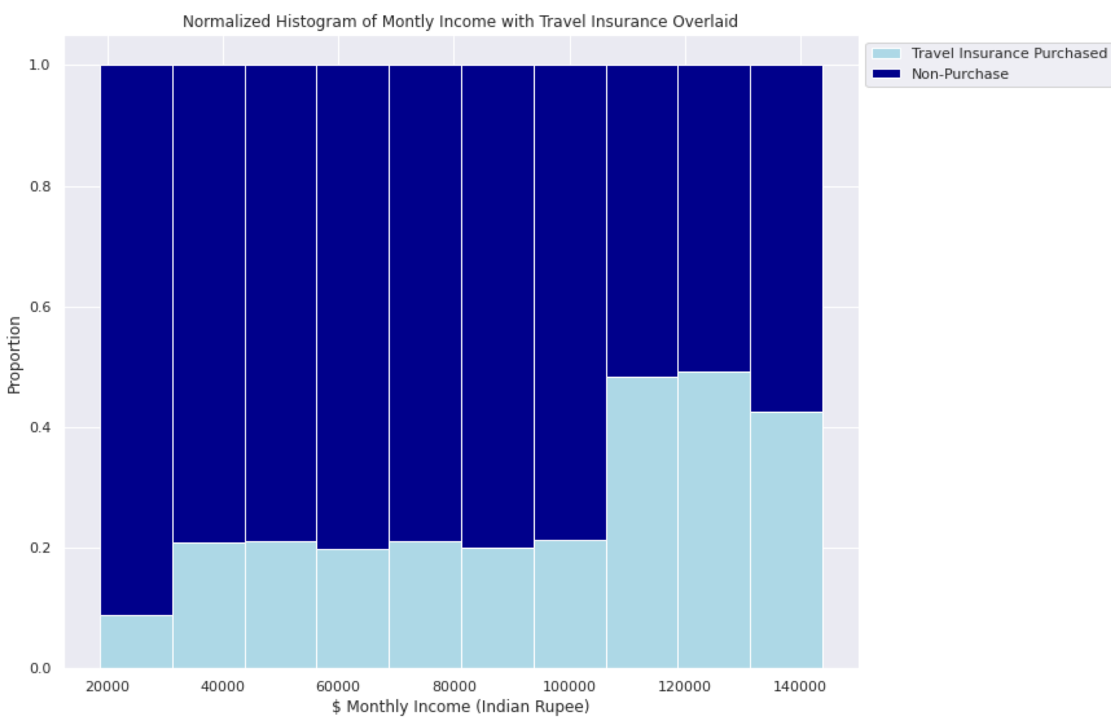
[12]:
```
# Counts by Monthly Rupee
n = np.array([[20.,  63.,  60.,  67.,  41.,  67.,  74., 191.,  84.,  43.],
        [208., 239., 223., 273., 153., 268., 274., 204.,  87.,  58.]])

# Bins for Montly Rupee
bins= np.array([ 25000.,  37500.,  50000.,  62500.,  75000.,  87500., 100000.,
        112500., 125000., 137500., 150000.])

               # Create normalized histogram for groups by target overlay
n_table = np.column_stack((n[0], n[1]))  # stack the tables
n_norm = n_table / n_table.sum(
```

```
        axis=1)[:, None]  # create normalized tables by sum
ourbins = np.column_stack((bins[0:10], bins[1:11]))  # create table bins

p1 = plt.bar(x=ourbins[:, 0],
                 height=n_norm[:, 0],
                 width=ourbins[:, 1] - ourbins[:, 0],
                 color="lightblue")  # first bar chart
p2 = plt.bar(
        x=ourbins[:, 0],
        height=n_norm[:, 1],
        width=ourbins[:, 1] - ourbins[:, 0],  # second bar chart
        bottom=n_norm[:, 0],
        color="darkblue")
    # Annotate legend, title with x and y labels
plt.legend(['Travel Insurance Purchased', 'Non-Purchase'],
               bbox_to_anchor=(1, 1))
plt.title('Normalized Histogram of Montly Income with Travel Insurance␣
 ↪Overlaid')
plt.xlabel('$ Monthly Income (Indian Rupee)')
plt.ylabel('Proportion')
plt.show()
```



4.4 Side-by-side Box-plots between Annual Income and Different Attributes

Python code:

[13]:
```
def make_boxplots(df, x):
    '''
    Takes in 'x' as a column from data frame 'df'
    and returns a side by side box-plot of
    x on the x-axis and AnnualIncome on the y-axis
    seperated by different colors noted by TravelInsurance

    '''

    # Palatte to color the target variable
    palatte = {0: "darkblue", 1: "lightblue"}

    # Change x-axis labels if age_groups or GraduatedOrNot
    order = None
    if x == "Age_Groups":
        order = ["20s", "30s"]
    if x == "GraduateOrNot":
        order = ["No", "Yes"]

    #Convert AnnualIncome to Monthly
    df['Monthly_Income'] = round(df['AnnualIncome']/12,2)

    # Boxplot
    sns.boxplot(x=x,
                y="Monthly_Income",
                hue="TravelInsurance",
                data=df,
                order=order,
                palette=palatte)

    # Legend properties
    top_bar = mpatches.Patch(color='darkblue', label='Non-purchase')
    bottom_bar = mpatches.Patch(color='lightblue',
                                label='Travel Insurance Purchased')
    plt.legend(handles=[top_bar, bottom_bar],
               bbox_to_anchor=(1.05, 1),
               loc=2,
               borderaxespad=0.)

    # Graph Properties
    plt.title(x + " vs. Montly Income with Travel Insurance Overlaid ")
    plt.xlabel(x)
    plt.ylabel("$ Monthly Income (Indian Rupee)")
```

```
    # Change ticks on x-axis for ChronicDiseases column
    if x == "ChronicDiseases":
        chronicdiease = [0, 1]
        labels = ['No', 'Yes']
        plt.xticks(chronicdiease, labels)

    # show the graph
    plt.show()
```

[14]:
```
# call stacked bar chart function

5 Feature Engineering and Pre-Processing

- Invent new columns
- Handle missing values, outliers, correlated features, etc.

Python code:

- Bin age into age groups

[15]:
```
# Create function to categorize age groups
def age_groups(x):
    '''
    x: This is a value from df['Age']
    returns each as a new categorical value of 20s or 30s
    '''
    if x < 30:
        return '20s'
    else:
        return '30s'

# group age into 20s and 30s
df['Age'] = df['Age'].apply(lambda x: age_groups(x))
df = df.rename(columns = {'Age':'Age_Groups'})
df.head()
```

[15]:
```
  Age_Groups                Employment Type GraduateOrNot  AnnualIncome  \
0        30s               Government Sector           Yes        400000
1        30s  Private Sector/Self Employed           Yes       1250000
2        30s  Private Sector/Self Employed           Yes        500000
3        20s  Private Sector/Self Employed           Yes        700000
4        20s  Private Sector/Self Employed           Yes        700000

   FamilyMembers  ChronicDiseases FrequentFlyer EverTravelledAbroad  \
0              6                1            No                  No
1              7                0            No                  No
2              4                1            No                  No
3              3                1            No                  No
4              8                1           Yes                  No

   TravelInsurance  Monthly_Income
0                0        33333.33
1                0       104166.67
2                1        41666.67
3                0        58333.33
4                0        58333.33
```

- Create poor- lower - middle - high income classes

[16]:
```python
# Create function to categorize wealth groups
def wealth_groups(x):
    '''
    x: This is a value from df['Monthly_Income']
    returns each as a new categorical value of 20s or 30s

    The range for categorizing income class

    - Poor Class:  2500- 6500 per month

    - Lower Class:  6500- 15000 per month

    - Middle Class:  15000- 100000 per month

    - Upper Class:  100000- 350000 per month

    '''

    if x <= 6500:
        return 'poor'
    elif x <= 15000:
        return 'lower'
    elif x <= 100000:
        return 'middle'
```

```
    else:
        return 'upper'

# group Monthly Income into wealth groups
df['AnnualIncome'] = df['Monthly_Income'].apply(lambda x: wealth_groups(x))
df = df.drop('Monthly_Income', axis = 1)
df = df.rename(columns = {'AnnualIncome':'Income_Class'})
df.head()
```

[16]:

```

6 Data splitting

- Training, validation, and test sets
- Since there does not exist a class imbalance problem, we split the data set into 75% training and 25% validation.

Python code:

[20]:
```python
# Response Variable
outcome = 'TravelInsurance'
y = df[outcome]

# features - Do not use Target_B or Target_D
predictors = [
    'GraduateOrNot', 'ChronicDiseases', 'FrequentFlyer', 'EverTravelledAbroad',
    'Age_Groups_20s', 'Age_Groups_30s', 'Employment Type_Government Sector',
    'Employment Type_Private Sector/Self Employed', 'Income_Class_middle',
    'Income_Class_upper', 'Household_Size_medium', 'Household_Size_small'
]
X = df[predictors]
```

```python
# Set seed to 1 and split on 30% validation
train_X, valid_X, train_y, valid_y = train_test_split(X,
                                                      y,
                                                      test_size=0.25,
                                                      random_state=1)

# Check dimensions
train_X.shape, valid_X.shape
```

[20]:
```
